1 Rotational Control Apparatus

CROSS REFERENCE

 The present application is a continuation-in-part of
 application Serial No. 08/254,290 filed June 6, 1994,
5 which is a continuation-in-part of application Serial No.
 08/201,783 filed February 25, 1994.

BACKGROUND

 The present invention generally relates to rotational
 control apparatus such as clutches and brakes, relates
10 particularly to clutches, relates more particularly to fan
 clutches, and relates specifically to fan clutches having
 multiple speed drives and/or which are shock resistant for
 high torsional and vibration conditions.

 Although fan clutches of the type shown in Figures 1-3
15 of U.S. Patent 4,425,993 and in Patent Nos. 4,226,095 and
 4,877,117 have proven to provide precise power,
 exceptional economy and dependable, long-lived durability,
 there exists a need to provide improvements to result in
 a further advantageous clutch. Specifically, a need
20 exists to provide a multiple speed drive clutch for the
 fan blades mounted thereon. In particular, in a typical
 fan clutch application for a truck, while the truck is
 traveling down the road, the engine is operating at
 relatively high RPMs and air is rapidly passing by the
25 radiator due to the movement of the truck. Thus, it is
 not necessary that the fan blades be driven at engine
 speed under these conditions, and it is advantageous to
 drive the fan blades at slower speeds or to stop fan
 rotation for at least noise and/or power consumption
30 reduction reasons. However, when the truck is parked and
 the engine is idling, maximum cooling is required such
 that the fan blades are driven at engine speed (or even
 faster than engine speed). Similarly, cooling requirements
 for other large engines such as for earth moving equipment
35 or like applications and even for stationary applications

1 vary according to various factors including ambient temperature, air flow, engine speed, and the like.

Further, the axially displaceable components of a fan clutch are subjected to high torsional and vibration
5 conditions due to its interconnection to the crank shaft of the engine which is rotated by the reciprocating action of pistons. High torsional and vibration conditions result in loss of tolerance in the axially displaceable components in preventing relative rotation between the
10 components and in the reduction of the clutch life. Thus, a need exists to provide a clutch which provides a dampening effect within the clutch to increase dependability and long-lived durability and having components which would be damaged by excessive torsional and
15 vibration stress and/or loads being normally replaceable to increase economy.

SUMMARY

The present invention solves these needs and other problems in the field of rotational control apparatus
20 and particularly fan clutches by providing, in the most preferred form, an eddy current drive in addition to an axially displaceable friction ring which engages with a friction disc, with the output portion of the clutch being driven by the friction disc and ring when engaged and being
25 driven by the eddy current drive when the friction disc and ring are disengaged. In a first aspect of the most preferred form of the present invention, the friction ring is axially engaged by fluid pressure introduced in the pressure cylinder defined by a piston for moving the
30 piston and such that separate controls are not necessary for the eddy current drive.

In further aspects of preferred forms of the present invention, the eddy current drive is mounted in the clutch in a manner to reduce the number of clutch components and
35 minimize the overall axial length and radial size. Specifically, one of the drive components of the eddy current drive is mounted to the input portion of the clutch while the other component is mounted directly on the friction interface member of the output portion for

1 axial movement therewith in a first form or is mounted on
the housing rotatably related to the friction interface
member of the output portion in an alternate form. In
one of the most preferred forms, the eddy current drive
5 is located at the same radial spacing from the clutch axis
as the friction ring.

In another aspect of a preferred form of the present
invention, a hub rotatable relative to a shaft is
rotatably related to the shaft when the input is not
10 rotatably related to the friction disc which is slideably
mounted on and rotationally related to the hub. In the
most preferred form, the shaft is stationary and it is an
aim of the present invention to brake the output portion
to prevent the fan blades from windmilling and from being
15 driven by an eddy current drive.

In a further aspect of the present invention, air flow
is created between the first and second drive components
of the rotational control apparatus by vanes which rotate
with the input. In the preferred forms, the output
20 includes openings located radially inward of the first and
second drive components through which the air flow between
the first and second drive components passes. In the most
preferred form, the vanes are mounted radially outward of
the first and second drive components and in particular to
25 the annular support which mounts the drive component to
the input.

It is thus an object of the present invention to
provide a novel rotational control apparatus.

It is further an object of the present invention to
30 provide such a novel rotational control apparatus in the
form of a fan clutch.

It is further an object of the present invention to
provide such a novel rotational control apparatus having
ease of serviceability.

35 It is further an object of the present invention to
provide such a novel rotational control apparatus which
includes a multiple speed drive.

1 It is further an object of the present invention to provide such a novel rotational control apparatus having reduced noise.

5 It is further an object of the present invention to provide such a novel rotational control apparatus having reduced squeal.

It is further an object of the present invention to provide such a novel rotational control apparatus having reduced power consumption.

10 It is further an object of the present invention to provide such a novel rotational control apparatus which is shock resistant for high torsional and vibration conditions.

15 It is further an object of the present invention to provide such a novel rotational control apparatus having an improved axially displaceable friction ring which provides a dampening effect within the apparatus.

20 It is further an object of the present invention to provide such a novel rotational control apparatus including components which would be damaged by torsional and vibration stress and/or loads to be normally replaceable.

25 It is further an object of the present invention to provide such a novel rotational control apparatus preventing fan blades mounted to the output portion of the clutch from windmilling.

30 It is further an object of the present invention to provide such a novel rotational control apparatus including components which rotatably relate the output portion to a further portion than the input portion.

It is further an object of the present invention to provide such a novel rotational control apparatus including an eddy current drive.

35 It is further an object of the present invention to provide such a novel rotational control apparatus including an eddy current drive which is overridden by braking components.

1 It is further an object of the present invention to provide such a novel rotational control apparatus designed to be simple.

5 It is further an object of the present invention to provide such a novel rotational control apparatus which is reliable.

It is further an object of the present invention to provide such a novel rotational control apparatus of a multi-speed design which reduces the number of clutch
10 components.

It is further an object of the present invention to provide such a novel rotational control apparatus of a multi-speed design which minimizes the overall axial length and radial size.

15 It is further an object of the present invention to provide such a novel rotational control apparatus having enhanced cooling of the drive components.

It is further an object of the present invention to provide such a novel rotational control apparatus
20 including vanes which create air flow between the drive components.

These and further objects and advantages of the present invention will become clearer in light of the following detailed description of illustrative embodiments
25 of this invention described in connection with the drawings.

DESCRIPTION OF THE DRAWINGS

The illustrative embodiments may best be described by reference to the accompanying drawings where:

30 Figure 1 shows a cross-sectional view of a rotational control apparatus in a first, preferred form of a fan clutch according to the preferred teachings of the present invention.

Figure 2 shows a partial, cross-sectional view of the
35 rotational control apparatus of Figure 1 according to section line 2-2 of Figure 1.

1 Figure 3 shows a partial, cross-sectional view of a rotational control apparatus in a second, preferred form of a fan clutch according to the preferred teachings of the present invention.

5 Figure 4 shows a partial, cross-sectional view of the rotational control apparatus of Figure 3 according to section line 4-4 of Figure 3.

 Figure 5 shows a cross-sectional view of a rotational control apparatus in a third, preferred form of a fan clutch according to the preferred teachings of the present invention.

 Figure 6 shows a partial, cross-sectional view of the rotational control apparatus of Figure 5 according to section line 6-6 of Figure 5.

15 Figure 7 shows a cross-sectional view of a rotational control apparatus in a fourth, preferred form of a fan clutch according to the preferred teachings of the present invention.

 Figure 8 shows an end elevational view of the annular body portion of the rotational control apparatus of Figure 7.

 Figure 9 shows a partial, end elevational view of the annular support of the rotational control apparatus of Figure 7, with portions broken away to show the internal construction.

25 Figure 10 shows a partial, end elevational view of the fan mount of the rotational control apparatus of Figure 7.

 The figures are drawn for ease of explanation of the basic teachings of the present invention only; the

1 extensions of the Figures with respect to number, position,
relationship, and dimensions of the parts to form the
preferred embodiment will be explained or will be within
the skill of the art after the following teachings of the
5 present invention have been read and understood. Further,
the exact dimensions and dimensional proportions to
conform to specific force, weight, strength, and similar
requirements will likewise be within the skill of the art
after the following teachings of the present invention
10 have been read and understood.

Where used in the figures of the drawings, the same
numerals designate the same or similar parts. Furthermore,
when the terms "first", "second", "internal", "radial",
"axial", "inward", "outward", and similar terms are used
15 herein, it should be understood that these terms have
reference only to the structure shown in the drawings as
it would appear to a person viewing the drawings and are
utilized only to facilitate describing the invention.

DESCRIPTION

20 Rotational control apparatus according to the
preferred teachings of the present invention is shown in
Figures 1-4 of the drawings in the preferred form of a fan
clutch and is generally designated A. In most preferred
embodiments of the present invention, clutch A is an
25 improvement of the type shown and described in Figures 1-3
of U.S. Patent No. 4,425,993. For purpose of explanation
of the basic teachings of the present invention, the same
numerals designate the same or similar parts in the present
Figures 1-4 and the figures of U.S. Patent No. 4,425,993.
30 The description of the common numerals and clutch A may be
found herein and in U.S. Patent No. 4,425,993, which is
hereby incorporated herein by reference.

Referring to the drawings in detail, fluid engaged
spring released clutch A includes an annular mount 12
35 having an annular flange 14 which is formed with a series
of spaced holes 16 for bolting or otherwise attaching
annular mount 12 to a sheave or other driven member which

1 is rotated about a clutch axis by a conventional mechanism (not shown) within the engine block. Flange 14 terminates radially inwardly in a hollow hub portion 24 formed with splines 26 thereon.

5 Further provided is a friction disc 28 including a circular main body portion 30 having an annular friction engageable surface or portion 34. Disc 28 is formed with an axial hollow hub 37 formed with internal splines 38 in engagement with splines 26 of hub portion 24. Mount 12
10 is secured and fixed in a splined relationship to body portion 30 of friction disc 28 by means of an axially mounted bolt 40 threadedly engaged in a clamping disc 42 through an axial hole 44 of hub portion 24.

Disc 42 has an annular flange portion 46 in secure
15 engagement with an annular recess 48 formed in body portion 30. Hub portion 24 is formed with an external annular recess 50. A housing hub 52 is formed with a companion annular recess 54, with the inner race 56 of a bearing 58 press fit in recess 50 and the outer race 60 of
20 bearing 58 press fit in recess 54. Bearing 58 is retained in recess 54 by means of a retaining ring 59 and in recess 50 by hub 37.

Hub 52 is part of a first outer shell housing 62, with hub 52 terminating in an annular and radially extending
25 body portion 64 which terminates in an offset portion 66 located radially outward of friction disc 28 and extending axially from body portion 64 beyond surface 34 of friction disc 28. A second outer shell housing 68 includes an annular main body portion 70 formed with an axial hole 72
30 terminating outwardly in an annular recess 74. Main body portion 70 terminates radially outwardly in a right angular flange 76. First outer shell housing 62 is secured to second outer shell housing 68 by means of spaced bolts 78. Thus, housings 62 and 68 are rotatable
35 relative to friction disc 28 by bearing 58 about the clutch axis.

1 An annular piston 80 includes a circular and center
body portion 82 which terminates in an outwardly offset
and radially disposed annular flange portion 84. An inner
annular surface 88 of annular flange 84 forms a cylindrical
5 surface. Formed internally of main body portion 70 of
shell housing 68 is an annular flange portion 90 slideably
positioned relative to surface 88 of flange 84. On the
outer surface of portion 90 is formed an annular recess 92
in which is positioned an O-ring 94 in sealing engagement
10 with surface 88 of flange 84 thereby forming a pressure
cylinder C.

Positioned within axial hole 72 is a rotary air union
96 which includes a substantially cylindrical body 98
having an annular shoulder 100 which fits in annular
15 recess 74 and sealed by an O-ring 102. Rotary air union
96 is secured in axial hole 72 and annular recess 74 by
means of a circular flat ring 104 secured upon the outer
surface of body portion 70 of second shell housing 68 by
means of spaced bolts 106 and in abutment with and upon
20 annular shoulder 100 of air union 96.

Rotatably received within cylindrical body 98 is a
stationary air union portion 118 formed with an axial hole
120 which terminates in a right angularly disposed hole
122 connected by a union 124 to a fluid supply line, not
25 shown. Air union portion 118 has mounted thereon a
suitable bearing which is within air union body 98 whereby
the entire clutch A may rotate about the clutch axis about
stationary air union portion 118, with rotary air union 96
providing fluid communication with cylinder C.

30 A series of bolts 148 are threadably engaged in first
shell housing 62 and each extend through a hole in the
spider hub portion of fan blades, not shown.

In the form shown in Figures 1 and 2, a friction
ring 86 is mounted on portion 82 such as by screws 87 in
35 axial alignment with frictional engagement portion 34 of
friction disc 28. In the form shown in Figures 1 and 2,
a series of spaced torque pins 132 are slideably mounted

1 on one end in a bushing 134 which is secured by press
fitting in body portion 70 of second shell housing 68.
The other ends of torque pins 132 are threaded or other-
wise secured in a hole 136 formed in piston 80. A series
5 of spaced return springs 138 are mounted on one end in a
hole 140 formed in offset portion 66 of first outer shell
housing 62. The other ends of return springs 138 are
mounted in a recess 142 formed in a tab 144 formed in the
outer periphery of piston 80 and extending into a void 146
10 formed between shell housings 62 and 68. It will be seen
that the springs 138 normally urge piston 80 and friction
facing ring 86 thereon from friction portion 34 of
friction disc 28.

Clutch A as described thus far is generally of the
15 type shown and described in U.S. Patent No. 4,425,993.
However, it can be appreciated that other constructions
may be applicable to utilize the teachings of the present
invention including but not limited to the construction
shown in Figures 5-10.

20 In most preferred forms of the present invention,
circumferentially spaced cooling vanes or fins 220 are
integrally formed and extend axially from the axial side
of body portion 30 opposite to friction engageable portion
34 and located radially intermediate hub 37 and the outer
25 periphery of body portion 30. Circumferentially spaced
air vent openings or apertures 222 are formed in body
portion 64 at a radial spacing from hub 52 corresponding
to and in alignment with cooling fins 220.

In a further, preferred form of clutch A of the
30 present invention as shown in Figures 3 and 4, offset
portion 66 of housing 62 includes internal, axially
extending gear teeth 250. A fiber friction ring 252 is
further provided including axially extending gear teeth
254 on its outer periphery. Teeth 254 are in gearing
35 relation with teeth 250. Thus, teeth 250 and 254 define
interfitting portions formed on housing 62 and friction
ring 252, respectively, to rotatively fix friction ring
252 to offset portion 66 and housing 62 but allow friction

1 ring 252 to be axially displaceable relative to offset
portion 66 and housing 62. Friction ring 252 is biased
away from friction disc 28 by means of a series of springs
256. Springs 256 are mounted in one end of a hole 258
5 formed in offset portion 66 circumferentially intermediate
teeth 250 such that springs 256 are within the radial
extent of teeth 250. The other end of springs 256 abut
with friction lining 252.

Alternate forms of rotational control apparatus
10 according to the preferred teachings of the present
invention are shown in Figures 5-10 of the drawings in
the preferred form of a fan clutch and are generally
designated A'. In most preferred embodiments of the
present invention, clutch A' is an improvement of the
15 type shown and described in U.S. Patent Nos. 4,226,095;
4,877,117; and 5,059,161. For purpose of explanation of
the basic teachings of the present invention, the numerals
including a prime (') notation in Figures 5-10 designate
the same or similar parts for the same numeral notation in
20 the figures of U.S. Patent Nos. 4,226,095; 4,877,117; and
5,059,161. The description of the same or similar parts
and clutch A' may be found herein and in U.S. Patent Nos.
4,226,095; 4,877,117; and 5,059,161, which are hereby
incorporated herein by reference.

25 Referring to the drawings in detail, clutch A'
includes a first output member to be driven in the form of
an annular piston 10' which has formed thereon the annular
friction disc 12' and the internal annular base portion
14'. Formed internally of annular base portion 14' are
30 the torque transmitting surfaces in the form of internal
splines 16' which engage with the external torque
transmitting surfaces in the form of splines 18' of the
hub 20'. Thus, friction disc 12' is slideably mounted on
and rotationally related to hub 20' by splines 16' and 18'.
35 The hub 20' is rotatably mounted on the reduced outward
end 22' of stationary shaft 24' by means of the bearings
26' and 28'.

1 The numeral 30' designates an annular cylinder block
in which is slideably mounted the annular piston 10' with
sealing engagement by means of the O-ring 32' mounted in
the annular groove formed in the piston 10' and the
5 O-ring 36' mounted in the annular groove 38' formed in the
cylinder 30'. The cylinder 30' is secured and rotationally
related to the hub 20' by means of a multiplicity of
spaced bolts 40' which extend through clearance holes 30a'
in the cylinder block 30' and engage threaded holes 41a'
10 in hub 20'. Air pressure is introduced through shaft 24'
and into cylinder C by conventional conduit means 42'
including a suitable rotary union.

Mounted on the hub 20' are the bearings 146' and 148'
which rotatably mount an input in the form of the sheave
15 50' which is typically driven by the engine crank shaft
by belts. The numeral 62' designates a washer slideably
received on hub 20' and sandwiched between splines 18' and
bearing 146'. Further provided is the compression coil
spring 56' sandwiched between washer 62' and piston 10'.
20 Friction facing ring 86 is mounted on the side of sheave
50' such as by screws 87 in axial alignment with annular
friction engagable surface or portion 34 on friction
disc 12'. In the most preferred form, a steel ring 235
is sandwiched between ring 86 and sheave 50'. The facing
25 86 engages the annular friction engagable portion 34 when
air pressure is introduced into cylinder C thereby
clutching in and rotatably relating the friction disc 12',
the hub 20' and the cylinder block 30' on which fan blades
of a fan 300 may be mounted on the pilot extension 53' and
30 secured by means of nut-equipped studs 55' on the cylinder
block 30'. With facing 86 engaging annular friction
engagable portion 34, hub 20', cylinder block 30' and fan
300 mounted thereon will rotate at the same speed or in
other words a 1:1 ratio with respect to sheave 50'.
35 Clutches A and A' according to the preferred teachings
of the present invention further include an eddy current
drive 224 between the input and output portions of

1 clutches A and A'. Specifically, in the preferred form,
drive 224 includes a first drive component shown as a
plurality of circumferentially spaced permanent magnets
226 radially spaced from the rotation axis of clutch A or
5 A'. In the most preferred form, magnets 226 are in the
form of discs and are radially oriented and held at
circumferentially spaced locations with alternating
polarity to the input by an annular magnetic holder 228
including a plurality of apertures 230 formed therein for
10 receipt and holding of magnets 226. Holder 228 is formed
from generally nonmagnetic material such as aluminum for
magnetically isolating magnets 226 in holder 228 from each
other. In clutches A of Figures 1-4 of the most preferred
form, holder 228 and magnets 226 mounted therein are
15 mounted to an axially inner, radially oriented or
extending surface 232 of body portion 30 of friction disc
28 opposite to friction engageable portion 34 and radially
spaced outwardly from fins 220 such as by axially extending
screws 234. In clutch A' of Figure 5 of the most preferred
20 form, holder 228 and magnets 226 mounted therein are
mounted to an axially inner, radially oriented or extending
surface 232 of the side of sheave 50' radially outward of
friction facing ring 86. In clutch A' of Figure 7 of the
most preferred form, holder 228 and magnets 226 mounted
25 therein are mounted to a radially oriented or extending
surface 232 on the opposite axial side of annular friction
disc 12' than surface 34. Sandwiched between surface 232
and holder 228 including magnets 226 is a ring 236 formed
of magnetic flux conductive material such as steel, with
30 screws 234 extending through suitable apertures formed in
ring 236. In clutch A' of Figure 5, rings 235 and 236 can
be integrally formed together or as separate components.

In the preferred form, magnets 226 are generally in
the form of circular discs as best seen in Figures 2 and 6.
35 In clutch A' of the most preferred form as shown in Figures
5 and 7, the discs are generally oval shape and include
first and second surfaces 237 located along parallel chords
of the circular shape on opposite sides and equally spaced
from the center of the circular shape. First and second

1 surfaces 237 are arranged generally perpendicular to a
radius from the clutch axis. Thus, the overall radial
size of holder 228 and of eddy current drive 224 can be
minimized to allow clutch A' of the present invention
5 including eddy current drive 224 to be easily substituted
in prior installations utilizing the clutches of the type
disclosed in Patent Nos. 4,226,095; 4,877,117; and
5,059,161 or the like.

Drive 224 further includes a second drive component
10 shown as a smooth ring 238 formed of electrically
conductive material such as copper and in the most
preferred forms is radially oriented. In clutches A of
Figures 1-4 of the most preferred form, ring 238 is
mounted on the output portion spaced radially outward of
15 friction engageable portion 34 at a radial location
corresponding to magnets 226 such as by screws 240 to the
axial surface of body portion 64 of housing 62 and spaced
radially outward of air vent apertures 222 at the radial
location corresponding to magnets 226.

20 In clutch A' of Figures 5-10 of the most preferred
form, ring 238 is mounted such as by screws 240 to the
axial surface of an annular body portion 241. In clutch
A' of Figure 5, annular body portion 241 is mounted on
the output portion and specifically is secured to friction
25 disc 12' such as by bolts 243. In clutch A' of Figure 7
of the most preferred form, annular body portion 241 is
mounted on the input portion and specifically is secured
to sheave 50' such as by an annular support 244. In the
most preferred form, annular support 244 includes a first
30 annular disc portion 260 sandwiched between ring 235 and
the side of sheave 50' and which is secured therebetween
by screws 87. Annular support 244 further includes a
second annular disc portion 262 located parallel to but
spaced from annular disc portion 260. Air moving vanes
35 264 are sandwiched between and secured to disc portions
260 and 262 at circumferentially spaced locations.
Annular support 244 is in turn secured to annular body
portion 241 by screws 246 extending through portions 260
and 262 intermediate vanes 264 of support 244 and threaded

1 into annular body portion 241. Disc portion 260 and ring
235 can be integrally formed together or as separate
components. A ring 242 formed of magnetic flux conductive
material such as steel is sandwiched between ring 238 and
5 body portion 64 or 241, with screws 240 extending through
suitable apertures formed in ring 242. Annular body
portion 241 is formed of aluminum and acts as a heat sink.
Therefore, as heat is drawn to annular body portion 241
from rings 238 and 242, radiation heating of magnets 226
10 by ring 238 is minimized.

Circumferentially spaced cooling fins 248 may be
provided on annular body portion 241 opposite rings 238
and 242 for cooling ring 238. According to the preferred
teachings of the present invention, fins 248 are
15 configured to achieve both angular and perpendicular air
flow. Specifically, in the most preferred form, fins 248
in the first and third quadratures 241a and c are arranged
at an acute angle in the order of 30° from radial lines in
the direction of rotation whereas fins 248 in the second
20 and fourth quadratures 241b and d are arranged along
radial lines from the clutch axis. It should be
appreciated that fins 248 must also be configured in a
manner which does not interfere with fan 300 which in the
most preferred form is not supplied with clutch A' and
25 specifically must be configured so as to allow relative
rotation between fan 300 and annular body portion 241
whatever type of fan 300 is mounted on clutch A'.

Because fan 300 is not supplied with clutch A' in the
most preferred form and to insure that air flow is allowed
30 past the front of cylinder block 30' and radially inward
of drive 224 and fins 248 independent of the actual fan
300 mounted on cylinder block 30', a fan mount 266 is
provided with clutch A' in the most preferred form. In
particular, mount 266 includes a central annular portion
35 268 of a diameter for slideable receipt and mounting on
pilot extension 53' of cylinder block 30'. Mount 266
further includes an outer annular portion 270 of a size

1 larger than annular portion 268. Circumferentially spaced
legs 272 integrally extend between portions 268 and 270
to hold them in a spaced, concentric arrangement. In the
most preferred form, annular portion 270 has an axial
5 thickness less than that of legs 272 and/or portion 268 to
form a pilot extension for slideable receipt of fan 300.
Bolts 274 can be provided extending through fan 300 and
threaded into portion 270 for securing fan 300 to mount
266. Mount 266 in turn can be secured to cylinder block
10 30' by studs 55' extending through annular portion 268
and/or legs 272. It can then be appreciated that air flow
is allowed through openings defined by and intermediate
annular portions 268 and 270 and legs 272.

It should be appreciated that the construction of
15 clutches A and A' according to the preferred teachings
of the present invention is believed to be advantageous.
Specifically, considerable heat can be generated by
slippage of friction disc 28 and 12' and friction ring 86
or 252. Further, heat is also generated by the rotation
20 of magnets 226 relative to rings 238 and 242. Friction
disc 12' or 28 or sheave 50' acts as a heat sink to draw
heat away from magnets 226. Likewise, annular portion 241
acts as a heat sink to draw heat from rings 238 and 242
and thus away from magnets 226. Additionally, rotation
25 of cooling vanes or fins 220 with friction disc 28 pulls
air into housings 62 and 68 to provide cooling to eddy
current drive 224 and specifically providing air flow
intermediate the components of eddy current drive 224
and particularly intermediate magnets 226 and ring 238.
30 Likewise, rotation of cooling fins 248 and vanes 264 with
sheave 50' at all times when the engine is running
increases heat transfer from annular body portion 241.
In particular, fins 248 draw air from the front of
cylinder block 30' radially inward of drive 224 and in
35 the most preferred form intermediate annular portions 268
and 270 and legs 272 to provide cooling of body portion
241 by convection. Additionally, vanes 264 draw air from

1 the front of cylinder block 30' radially inward of drive
224 and in the most preferred form intermediate annular
portions 268 and 270 and legs 272 to provide cooling of
magnets 226 and ring 238 by convection. In this regard,
5 vanes 264 move the air outwardly to create a pressure
differential which draws air between magnets 226 and ring
238 to create air flow therebetween which would likely not
occur or would be practically non-existent if air movement
means would not be included. As the performance and life
10 of magnets 226 may be detrimentally affected by heat,
clutches A and A' according to the preferred teachings of
the present invention protect magnets 226 from excessive
heat conditions.

In operation of clutch A and assuming the input
15 portion of clutch A, i.e. mount 12, is being rotated by
conventional means hereinbefore referred to, the fan
blades are rotated about the axis of clutch A by
introducing fluid pressure through rotary air union 96
into cylinder C which forces piston 80 in the direction
20 towards friction disc 28 whereby the friction engagement

1 surface of friction ring 86 or 252 engages the friction
engagement surface of friction disc 28 to rotatably relate
the input and output portions of clutch A. As a result of
the above, which is contrary to the urging of springs 138
5 or 256, the output portion of clutch A, i.e. housings 62
and 68 with the fan blades thereon, are rotated generally
at the rotational speed of mount 12 and friction disc 28.
With the fluid pressure released, springs 138 or 256 urge
friction ring 86 or 252 from engagement with friction
10 disc 28 whereby friction ring 86 or 252 is separated or
disengaged from friction disc 28 such that the output
portion of clutch A is rotationally independent of the
input portion.

In operation of clutch A' and assuming the input
15 portion of clutch A', i.e. sheave 50', is being rotated
by conventional means hereinbefore referred to, the
fan blades are rotated about the axis of clutch A' by
introducing fluid pressure through conduit means 42'
into cylinder C which forces piston 10' in the direction
20 towards sheave 50' whereby the friction engagement surface
of friction ring 86 engages the friction engagement
surface or portion 34 to rotatably relate the input and
output portions of clutch A'. As a result of the above,
which is contrary to the urging of springs 56', the output
25 portion of clutch A', i.e. annular cylinder block 30'
with the fan blades thereon, are rotated generally at the
rotational speed of sheave 50'. With fluid pressure
released, springs 56' urge friction disc 12' from
engagement with friction ring 86 whereby friction ring 86
30 is separated or disengaged from portion 34 such that the
output portion of clutch A' is rotationally independent
of the input portion.

Due to their mounting on the input portions, magnets
226 of clutches A and A' of Figures 1-5 and ring 238 of
35 clutch A' of Figure 7 rotate at the rotational speed of
the input portions. Due to eddy current principles, forces
between magnets 226 and ring 242 induce rotation of the
output portions of clutches A and A'. The rotational
speed of the output portions of clutches A and A' is less

1 than the rotational speed of the input portions due to the
torque load placed upon the output portions by the fan
blades in the most preferred form. The rotational speed
of the output portions relative to the input portions is
5 then dependent upon the number and strength of magnets
226, the axial spacing between magnets 226 and rings 238
and 242, the speed of rotation of the input portions, and
the torque load placed upon the output portions.

It can then be appreciated that when greater cooling
10 requirements exist such as at low engine RPMs, fluid
pressure is introduced into cylinder C causing rotation
of the output portions and the fan blades thereon at the
rotational speed of the input portions which typically
will be at engine speeds. However, if lesser cooling
15 requirements exist such as at high engine RPMs, fluid
pressure is released causing rotation of the output
portions and the fan blades thereon at a rotational speed
less than the input portions through eddy current drive
224. It can further be appreciated that lower rotational
20 speeds of the fan blades result in reduced power
consumption and in reduced noise generation and thus is
very advantageous.

It should then be noted that permanent magnet eddy
current drives for fan clutches are known which provide
25 for fan rotation at speeds less than engine speed but
which do not provide direct drive with the engine speed.
Further, electromagnetically operable clutches are known
which provide for fan rotation at engine speed through a
first electromagnetic clutch and at lower than engine
30 speed through a second electromagnetic clutch via an eddy
current coupling. However, persons skilled in the art
did not recognize the synergistic results which are
obtainable utilizing a permanent magnet eddy current
drive in combination with a nonelectromagnetically
35 controlled clutch and specifically with a fluid and
particularly an air actuated clutch. In particular, it
should be noted when clutches A and A' of the present
invention shown in the Figures are actuated in the most
preferred form by the introduction of fluid pressure,

1 clutches A and A' of the present invention rotate the fan
blades at engine speeds with eddy current drive 224 and
specifically magnets 226 and holder 228 and also rings 238
and 242 rotating at engine speeds due to their connection
5 to output and input portions of clutches A and A'. Thus,
the engagement of annular friction engageable portion 34
with friction ring 86 or 252 overrides eddy current
drive 224 due to the simultaneous rotation of magnets 226
and rings 238 and 242. Thus, clutch A of the present
10 invention operates in the same manner as clutch A of
U.S. Patent No. 4,425,993 and clutch A' of the present
invention operates in the same manner as the clutches of
U.S. Patent Nos. 4,226,095; 4,877,117; and 5,059,161 when
friction ring 86 or 252 is axially displaced to engage
15 annular friction engageable portion 34. However, when
friction ring 86 or 252 is axially displaced from annular
friction engageable portion 34, clutches A and A' of the
present invention continue to drive the fan blades through
eddy current drive 224 whereas the clutches of U.S. Patent
20 Nos. 4,425,993; 4,226,095; and 4,877,117 provide no driving
connection to the fan blades. Specifically, due to their
mounting to the input portions, magnets 226 of clutches A
and A' of Figures 1-5 and ring 238 of clutch A' of Figure 7
rotate at engine speed whether or not portion 34 is engaged
25 by friction ring 86 or 252. Due to the magnetic attraction
of magnets 226 to ring 242, the output portions of
clutches A and A' are driven and rotate about the clutch
axis at a speed less than that of the input portions or
in other words at less than engine speed due to the torque
30 load placed on the output portions by the fan blades.
Thus, clutches A and A' of the present invention can
provide cooling at all times and specifically whether or
not friction disc 86 or 252 engages friction engageable
portion 34. It should further be appreciated that no
35 separate controls or other actuation are required for eddy
current drive 224 such that clutch A and A' of the present
invention can be easily substituted in prior installations
utilizing clutches of the type disclosed in U.S. Patent
Nos. 4,425,993; 4,226,095; and 4,877,117 or the like.

- 1 In particular, no electric controls such as would be necessary for electromagnetically operable drives are required according to the preferred teachings of the present invention. Specifically, when fluid actuated,
- 5 clutches A and A' of the present invention including eddy current drive 224 have the same operation as the clutches of U.S. Patent Nos. 4,425,993; 4,226,095; and 4,877,117 which do not include the eddy current drive. However, in the absence of fluid pressure and without actuation of any
- 10 kind, eddy current drive 224 is then revealed in clutches A and A' of the present invention to drive and rotate the fan blades rather than to simply let the fan blades be rotationally free as in the clutches of U.S. Patent Nos. 4,425,993; 4,226,095; and 4,877,117.
- 15 Furthermore, the particular construction of clutch A according to the teachings of the present invention is believed to be particularly advantageous. In this regard, clutch A of the present invention obtains similar advantages as those obtained by clutch A of U.S. Patent
- 20 No. 4,425,993. Additionally, eddy current drive 224 is included inside of housings 62 and 68 and is protected thereby from the environment or other outside forces. Even when housing 68 is removed from housing 62 to allow replacement of friction ring 86 or 252, eddy current
- 25 drive 224 is generally enclosed by housing 62 and friction disc 28 which typically remain in an assembled condition during replacement of friction ring 86 or 252. Further, eddy current drive 224 is included inside of clutch A with minimal or no increase in axial length and
- 30 specifically without requiring the addition of further disc or other mounting components. Specifically, magnets 226, holder 228, and ring 236 are mounted to friction disc 28, and rings 238 and 242 are mounted to housing 62, with housing 62 and friction disc 28 being necessary
- 35 components for providing direct drive actuation through friction ring 86 or 252.

It should also be noted that the construction of clutch A allows a single bearing 58 and specifically provides rigidity which braces outer race 60 of bearing 58

- 1 by supporting housings 62 and 68 through the engagement of
friction disc 28 and friction ring 86 or 252 by directing
load forces to friction disc 28 which in turn is directly
connected to the rigid support which is the shaft or other
5 rotatable member that mounts the entire clutch A.

Clutch A of the type as shown in Figures 3 and 4
is further believed to be particularly advantageous.
Specifically, when clutch A is utilized in its preferred
form as a fan clutch mounted on the crank shaft of an
engine such as, in the preferred form, a diesel engine,
10 clutch A is subjected to tremendous vibration stress
or loads due to the torsional modes set up by the
reciprocating action of the pistons of the engine.
This torsional vibration causes constant clatter in the
15 axially displaceable components of the clutch. When the
components allowing axial displacement are formed of metal
which typically is cast iron or aluminum with an anodized
hard coat surface, this constant clatter in the axially
displaceable, metal components results in the development
20 of a very sloppy fit in a relatively short period of time
thus reducing the life of the clutch. According to the
preferred teachings of the present invention, use of fiber
friction ring 252 acts as a dampener between housing 62
and friction disc 28. Specifically, friction ring 252 is
25 formed of friction brake material that is resilient enough
to absorb the torsional vibration and reform itself to
its original condition to withstand the punishment of
vibration stress or loads due to the torsional modes set
up by the reciprocating action of the pistons of an engine.
30 It can be appreciated that friction ring 252 can be
inexpensively fabricated at the desired axial thickness to
provide teeth 254 with the necessary bearing surface with
teeth 250 to transfer the desired torque levels without
damaging teeth 254. It should further be appreciated that
35 in the event of excessive vibration stress or loading,
failure will occur in teeth 254 of fiber friction ring
252 and not in the metal components such as teeth 250,
housings 62 and 68 or friction disc 28, with friction ring
252 being a normally replaceable part due to frictional

1 wear. It can then be appreciated that torque pins 132,
bushings 134, and holes 136 are not required in clutch A
of Figures 3 and 4 which are especially prone to the
development of sloppy fits, and also reducing the
5 complexity and weight of clutch A of Figures 3 and 4.

Similarly, clutch A' of the type as shown in Figures
5-10 is further believed to be particularly advantageous.
Particularly, eddy current drive 224 is included in clutch
A' with no increase in axial length and without requiring
10 the addition of further disc or other mounting components.
Specifically, magnets 226, holder 228, and rings 236, 238
and 242 are mounted to sheave 50' or to friction disc 12',
with sheave 50' and friction disc 12' being necessary
components for providing direct drive actuation through
15 friction ring 86. Furthermore, clutch A' of Figure 7
according to the preferred teachings of the present
invention is further believed to be advantageous since
eddy current drive 224 is included with minimal increase
in radial size since magnets 226 and rings 238 and 242 are
20 mounted at the same radial spacing from the clutch axis as
friction ring 86.

Further, when clutches A and A' are utilized in their
preferred form as a fan clutch, the fan blades of the
output portion are driven either due to the rotational
25 relation provided by the engagement of friction ring 86
or 252 with annular friction engagable portion 34 or by
eddy current drive 224 of the present invention. However,
there are occasions when it is desired that the fan blades
remain stationary. Clutch A' according to the preferred
30 teachings of the present invention includes provisions for
rotatably relating hub 20' to a further portion of clutch
A' which is stationary in the most preferred form and
specifically to shaft 24'. Specifically, shaft 24' is
secured to a radial flange mounting bracket 92' by any
35 suitable means. Clutch A' further includes an annular
piston 100' which is reciprocally received in a cylinder
cavity 102' formed in bracket 92'. Piston 100' is biased
into cavity 102' by a spring 104' sandwiched between a

1 stop 262 held axially on shaft 24'. Piston 100' is moved
in cavity 102' against the bias of spring 104' by fluid
pressure introduced through inlet 106' formed in bracket
92'. Piston 100' includes an integral friction disc 264.
5 Clutch A' according to the preferred teachings of the
present invention further includes an annular, radial
extension 266 secured to the end of hub 20' opposite
cylinder block 30' by any suitable means such as by screws
268. In the most preferred form, bearings 146' and 148'
10 are sandwiched on hub 20' between extension 266 and washer
62'. A friction ring 270 is removably secured to and
carried by extension 266 such as by screws 272. Friction
ring 270 is engaged by friction disc 264 when air pressure
is introduced into cavity 102' thereby rotatably relating
15 hub 20', bracket 92', and shaft 24' and thus braking the
fan blades secured to cylinder block 30' secured to hub
20' to prevent their windmilling due to the passing of air
over the fan blades and to prevent their being driven by
eddy current drive 224 in the most preferred form.
20 In operation of clutch A' of the most preferred form
of the present invention, the fan blades of fan 300 can be
rotated at engine speeds when fluid pressure is introduced
into cylinder C thereby rotatably relating sheave 50' to
hub 20'. In the preferred form, magnets 226 are axially
25 spaced from ring 238 when friction ring 86 engages with
annular friction engagable portion 34 which overrides eddy
current drive 224. In the absence of fluid pressure into
cylinder C and cavity 102', friction ring 86 is axially
spaced from portion 34. Although magnets 226 in clutch A'
30 of Figure 5 are further axially spaced from ring 238 than
when friction ring 86 was engaged with portion 34, the
spacing between magnets 226 and ring 238 is such that the
fan blades are driven by eddy current drive 224. It can
be appreciated that the axial spacing of magnets 226 from
35 ring 238 in clutch A' of Figure 7 actually increases when
friction ring 86 is engaged with portion 34 to avoid even
the possibility of a problem of magnets 226 contacting
ring 238 due to long-term frictional wear of friction

1 ring 86. If fluid pressure is introduced into cavity
102', eddy current drive 224 is also over-ridden as hub
20' is rotatably related to bracket 92' thus slowing and
stopping rotation of the fan blades. Suitable valving
5 should be provided to prevent fluid pressure from being
simultaneously introduced into cylinder C and cavity 102'.
It can then be appreciated that clutch A' according to the
teachings of the present invention provides three speeds
for the fan blades, i.e. at engine speed, at less than
10 engine speed, and stopped in the most preferred form.

Furthermore, when air actuated, i.e. when fluid
pressure is introduced into cylinder C, the force transfer
path through clutch A' is from friction ring 86, through
friction disc 12' to hub 20' through splines 16' and 18',
15 through bearings 146' and 148', through sheave 50', and
back to friction ring 86, with no relative rotation
occurring through bearings 146' and 148' between hub 20'
and sheave 50'. No actuation force occurs through
bearings 26' and 28'. Thus, substantially less force is
20 placed upon bearings 26' and 28' in the construction of
clutch A' according to the preferred teachings of the
present invention than through the bearings which mount
the hub in the clutches of U.S. Patent Nos. 4,226,095 and
4,877,117 which are in the actuation force path and with
25 the bearings which mount the sheave being subjected to
relative rotation at all times that the engine is running
thus increasing wear and decreasing life. The construction
of clutch A' of the preferred form further includes piston
10' having an increased cross-sectional area to allow
30 greater actuation pressure to be placed upon friction disc
12' with the same fluid pressure. This greater actuation
pressure allows the size of friction ring 86 to be
minimized while still providing the same degree of
actuation such that the overall diametric size of clutch
35 A' can be reduced from clutches of the type of Patent Nos.
4,226,095; 4,877,117; and 5,059,161 having corresponding
performance characteristics. Thus, clutch A' according
to the preferred teachings of the present invention is
able to fit in smaller installations or the same size

1 installations with eddy current drive 224 as prior
installations utilizing clutches of the type disclosed
in U.S. Patent Nos. 4,226,095; 4,877,117; and 5,059,161.

It should be noted that clutches A and A' according
5 to the preferred teachings of the present invention have a
construction which is very simple in nature, lends itself
to very economical manufacturing, and is very durable.

Now that the basic teachings of the present invention
have been explained, many extensions and variations will
10 be obvious to one having ordinary skill in the art. For
example, although clutch A is shown in Figures 3 and 4 in
the most preferred form including a multiple speed drive
and specifically eddy current drive 224 and is believed
to produce synergistic results, it can be appreciated
15 that clutch A of Figures 3 and 4 could be manufactured
without a multiple speed drive.

Further, clutch A of Figures 3 and 4 could be easily
changed to be spring engaged and fluid released. As an
example, friction disc 28 could be arranged to contact
20 the other side of friction ring 252 which is biased by
springs to engage friction disc 28 and which is disengaged
by fingers coming out from piston 80 and radially spaced
outwardly of friction disc 28.

Likewise, although shown and described for use as a
25 fan clutch, clutches A and A' and especially the clutch
of the form of Figures 3 and 4, according to the teachings
of the present invention, may be utilized in other
applications such as, but not limited to, for driving an
alternator, an air conditioner, or the like.

30 Furthermore, although clutch A' of Figures 5-10 in the
most preferred form includes eddy current drive 224 and
is believed to produce synergistic results, eddy current
drive 224 can be omitted with friction ring 270 and
friction disc 264 preventing windmilling when clutch A'
35 is not air actuated.

Likewise, although placement of the components of eddy
current drive 224 on the input and outputs of clutches A
and A' is believed to be advantageous in the particular

1 preferred forms shown, reversal of the components of eddy
current drive 224 on the input and output may be possible
according to the teachings of the present invention.

Thus since the invention disclosed herein may be
5 embodied in other specific forms without departing from
the spirit or general characteristics thereof, some of
which forms have been indicated, the embodiments
described herein are to be considered in all respects
illustrative and not restrictive. The scope of the
10 invention is to be indicated by the appended claims,
rather than by the foregoing description, and all changes
which come within the meaning and range of equivalency of
the claims are intended to be embraced therein.

What is claimed is:
